

MLBN Data Cleaning, Publishing and Analysis Process

Author: Ritzo, Chris
Date: 2021-04-29

Introduction

This document is intended to establish provenance of the measurements collected during the *Measuring Library Broadband Networks (MLBN)* program, funded by the Institute of Museum and Library Services (IMLS) National Leadership Grant for Libraries program (award #LG-71-18-0110-18).

Data Overview

Internet measurement test data collected by the measurement devices in the MLBN program was collected during the development of the Murakami software itself, which included changes to the output formats for supported tests and different NDT test client code used between program years. We generally refer to the data collected by program year 1 and 2, as we used two different software releases of Murakami in each year. Only data from the second program year between 2020-02-01 and 2021-01-31 were used for our analyses and final reporting. However, in this document we also outline the process used to prepare the data collected from the first program year as well.

Year 1 Data Collection Instruments

In year 1, Murakami used the following Internet measurement tests:

- [NDT](#) - Network Diagnostic Tool (using the [ndt5](#) protocol) provided by [Measurement Kit](#)
- [DASH](#) - Dynamic Adaptive Streaming over HTTP, provided by Neubot
- [speedtest-cli](#) - Community developed command line interface for testing internet bandwidth using speedtest.net

NDT and DASH measurements were conducted to the nearest M-Lab server. Speedtest measurements were conducted to the nearest OOKLA server. Because NDT and speedtest-cli are both throughput measurements, that NDT uses a single TCP stream for measurement, and speedtest-cli supports both single and multiple TCP streams, in year 1 we ran speedtest-cli measurements using a single stream to make these two measurements more comparable.

The NDT client library used was provided by Measurement Kit, a C++ application that provided multiple open source Internet measurement instruments. During program year 1, this library was

slated for deprecation by its maintainer. During this time, M-Lab also released replacement client libraries written in Go for two NDT protocols, [ndt5](#) and [ndt7](#).

Year 2 Data Collection Instruments

In year 2, Murakami used the following Internet measurement tests:

- [NDT \(v5\)](#) - Network Diagnostic Tool provided by [M-Lab](#)
- [NDT \(v7\)](#) - Network Diagnostic Tool provided by [M-Lab](#)
- [speedtest-cli \(single stream\)](#) - Community developed command line interface for testing internet bandwidth using speedtest.net
- [speedtest-cli \(multi-stream\)](#) - Community developed command line interface for testing internet bandwidth using speedtest.net

In the second program year, the NDT client from Measurement Kit was replaced with two client libraries provided by M-Lab. `ndt5-client-go` ran the `ndt5` protocol test, and `ndt7-client-go` ran the `ndt7` protocol test, each to the nearest M-Lab server. In addition to a single stream test with `speedtest-cli` we also conducted a multi-stream test. And finally, we removed the DASH test in year 2 since its maintainer (also the maintainer of Measurement Kit) shared that it may also be deprecated in the future.

Changes to the Murakami Software Across Program Years

The Murakami software can be thought of as an orchestrator for running the data collection instruments described above. Because one goal of the program itself was to improve the software itself, changes to the format of saved test results were changed during development. In year 1 data from each test was saved in the native formats provided by each client library. In order to make Murakami a more useful software to support structured data collection for research, in year 2 a standard schema for each supported measurement instrument was introduced.

The output schema for each instrument includes four metadata fields that can be provided by the user deploying Murakami device(s):

- *MurakamiDeviceID*
 - A generated ID for each Murakami device when using Balena
 - Required by Murakami Viz to connect a device's data to a specific location
- *MurakamiLocation*
 - Identifier for the location of the Murakami device
 - Added as an environment variable
 - Used as a metadata value on each saved test result, and in the test result file name
- *MurakamiConnectionType*
 - Identifier for the type of connection the Murakami device is measuring (i.e. wifi, ethernet)
 - Added as an environment variable

- Used as a metadata value on each saved test result, and in the test result file name
- *MurakamiNetworkType*
 - Identifier for the type of network the Murakami device is measuring (i.e. egress, public, staff)
 - Added as an environment variable
 - Used as a metadata value on each saved test result, and in the test result file name

As these schemas were rolled out, minor changes to other field names in the schema were made, and ultimately standardized.

The end result of the issues discussed above were:

- Inconsistent schema between tests in years 1 and 2
- Missing fields and contents in year 1 data that were added in year 2
- Minor field naming differences in some year 2 results

To address these issues, as part of the data preparation and cleaning for analyses, additional steps were made to ensure a consistent dataset covering both program years could be published and shared.

Data Preparation Methods

To clean and unify the data from each program year into a common schema, we used the standard output schema for Murakami's supported measurement instruments. Data collected in year 1 was first converted from JSONL to CSV format, using a utility script, *murakami-convert*. An updated version of *murakami-convert* is now included in the software itself. One CSV file was saved for each Murakami device. Each CSV was then opened using Libreoffice, and four metadata columns were added: *MurakamiDeviceID*, *MurakamiLocation*, *MurakamiConnectionType*, and *MurakamiNetworkType*. The values for these columns were primarily obtained from internal project documentation. All cleaned CSV files were then uploaded to Google Cloud Storage, and were loaded into the BigQuery tables: ``Y1_dash_import``, ``Y1_ndt_import``, and ``Y1_speedtest_import``.

Schema fields for test data collected in year 2 had mostly consistent formats, except in cases where:

- Field was named as plural and later changed to singular, such as *DownloadUnits* changed to *DownloadUnit*
- Field was initially named and then altered to be more specific, such as *RTTValue* changed to *MinRTTValue*
- Field was added to the schema, such as the addition of *MurakamiDeviceID*

Year 2 data for each measurement instrument was loaded into the following BigQuery tables: ``Y2_ndt5_import``, ``Y2_ndt7_import``, and ``Y2_speedtest_import``. The data in each of these

imported tables was then examined for rows missing the *MurakamiDeviceID* metadata field. Because this field was added to Murakami's output schemas late in the development process, many test rows did not contain this field. To preserve the data as imported, and to standardize names of fields across the archive, a query was written to re-format and add missing fields where needed, to filter for only test results that did not contain errors, and to save the results in a separate, final table to be used for analyses. The queries used and resulting table names are provided in **Appendix A**.

Datasets Used in Final Analyses

Limiting the scope of measurements in year 2 for final analysis

The MLBN team determined that our final analyses would focus on performance or “speed” measurements from different available tests. Since the DASH test is a measure of streaming, we decided to not run it in the second year. Additionally, we expanded the number of performance tests in the second year: NDT v5 and v7, and speedtest-cli single and multi-stream tests.

Deriving metadata tables from survey results, and source measurement tables

To enable richer analyses and visualizations of the data, we created three metadata tables/views:

- Device Metadata view
- Libraries Metadata table
- Libraries and Servers Coordinates view

To aid in the creation of the *Libraries and Servers Coordinates view*, an additional table (*mmlab_sites_20200707*) was created from an export of [M-Lab's site-info API](#) to more easily join the exact locations of M-Lab's servers for NDT test results.

Creating a final joined database view for visualization and analysis

Once all performance tests were loaded into individual import tables, a “view” was created using a query that unified all performance measurements in a single dataset.

Please see **Appendix B** for details on the creation of metadata tables and views, as well as the final joined database view.

Data Aggregation and Visualization in DataStudio Report

With cleaned data stored in Google BigQuery tables and views, the MLBN research team were able to easily aggregate and visualize the final dataset in an [interactive report](#) using Google's [DataStudio](#) platform.

Additional Traceroute Data Collected from Library Devices

In order to explore various facets of latency and routing after the completion of the MLBN program, traceroutes were gathered from one measurement device at each library participating in the program:

- To each M-Lab server through which an NDT test was conducted
- To each Ookla server through which a speedtest-cli test was conducted

First, the unified performance tests view was queried and used to retrieve a list of all unique server URLs for each library and test combination. We decided to use IP address for conducting the traceroutes, and wrote a small utility script, *get-ips.sh*, to lookup the IPs for all servers' hostnames. The result was a CSV mapping each server and IP address for each test. The unique IP address for NDT and Ookla servers for each library and test were created as CSV files. Finally, the relevant IP address files for NDT and Ookla test servers were uploaded to each egress device at each library, and traceroutes were conducted to each server in each list using another utility script, *run-traces.sh*. Each individual traceroute to each server was saved as an individual file, named with associated metadata using this format: *Library-test-IPaddress*. For example: *Andover-MA-ndt-128.177.119.203*.

While these traceroutes were not part of our final program analyses, it is the intention of MLBN researchers to use these data in the future to examine latency over the hops in the end to end path between MLBN libraries and Ookla and M-Lab servers.

Appendix A - Data Prep Queries

Year 1 test data

Measurement test:	speedtest-cli	<u># Rows</u>
Source import table:	Y1_speedtest_import	109406

Libraries Metadata table

This table was derived from surveys of participating libraries, desk research examining the public websites of participating libraries, and additional information from public APIs or services. The fields in this table are:

- library_name
- branch_location
- state
- imls_code
- MurakamiLocation

- Timezone
- Zipcode
- Lat_Lon
- Isp1Name
- Isp1type
- Isp1AccessMedia
- Isp1ConnectionType
- Isp1NetworkType
- Isp2Name
- Isp2type
- Isp2AccessMedia
- Isp2ConnectionType
- Isp2NetworkType
- Isp1ASN
- Isp1ASName
- Isp2ASN
- Isp2ASName
